RABIN-KARP ALGORITHM

Fingerprint idea

■ Assume:

- We can compute a fingerprint $f(P)$ of P in $O(m)$ time.
- If $f(P) \neq f(T[s .. s+m-1])$, then $P \neq T[s .. s+m-1]$
- We can compare fingerprints in $O(1)$
- We can compute $f' = f(T[s+1.. s+m])$ from $f(T[s .. s+m-1])$, in $O(1)$

Algorithm with Fingerprints

- Let the alphabet $\Sigma = \{0,1,2,3,4,5,6,7,8,9\}$
- Let fingerprint to be just a decimal number, i.e.,
 $f("1045") = 1*10^3 + 0*10^2 + 4*10^1 + 5 = 1045$

- **Fingerprint-Search**(T, P)

```
01 fp ← compute f(P)
02 f ← compute f(T[0..m-1])
03 for s ← 0 to n - m do
04     if fp = f return s
05     f ← (f - T[s]*10m-1)*10 + T[s+m]
06 return -1
```

- Running time $2O(m) + O(n-m) = O(n)$

Using a Hash Function

- Problem:
 - we can not assume we can do arithmetics with m-digits-long numbers in $O(1)$ time
- Solution: Use a hash function $h = f \bmod q$
 - For example, if $q = 7$, $h("52") = 52 \bmod 7 = 3$
 - $h(S1) \neq h(S2) \Rightarrow S1 \neq S2$
 - But $h(S1) = h(S2)$ does not imply $S1=S2$
 - For example, if $q = 7$, $h("73") = 3$, but $"73" \neq "52"$
- Basic “mod q ” arithmetics:
 - $(a+b) \bmod q = (a \bmod q + b \bmod q) \bmod q$
 - $(a*b) \bmod q = (a \bmod q)*(b \bmod q) \bmod q$

Preprocessing and Stepping

■ Preprocessing:

- $fp = P[m-1] + 10*(P[m-2] + 10*(P[m-3] + \dots + 10*(P[1] + 10*P[0])\dots)) \bmod q$
- In the same way compute ft from $T[0..m-1]$
- Example: $P = \text{"2531"} , q = 7 , fp = ?$

■ Stepping:

- $ft = (ft - T[s]*10^{m-1} \bmod q)*10 + T[s+m]) \bmod q$
- $10^{m-1} \bmod q$ can be computed once in the preprocessing
- Example: Let $T[\dots] = \text{"5319"} , q = 7$, what is the corresponding ft ?

Stepping

- $T = 25316446766\dots$, $m = 4$, $q=7$
- $T_0 = \text{"2531"}$
 - $ft = 2531 \bmod 7 = 4$
- $T_1 = \text{"5319"}$
 - $ft = ((ft - T[s] \cdot (10^{m-1} \bmod q)) \cdot 10 + T[s+m]) \bmod q$
 - $ft = ((ft - T[0] \cdot (10^3 \bmod 7)) \cdot 10 + T[0+4]) \bmod 7$
 - $= ((4 - (2 \cdot 1000 \bmod 7)) \cdot 10 + T[4]) \bmod 7$
 - $= ((4 - (2 \cdot 6)) \cdot 10 + 6) \bmod 7 = (-8 \cdot 10 + 9) \bmod 7$
 - $= -71 \bmod 7 = 6$
 - $5319 \bmod 7 = 6$

Rabin-Karp Algorithm

Rabin-Karp-Search(T, P)

```
01  $q \leftarrow$  a prime larger than  $m$ 
02  $c \leftarrow 10^{m-1} \bmod q$  // run a loop multiplying by 10 mod  $q$ 
03  $fp \leftarrow 0$ ;  $ft \leftarrow 0$ 
04 for  $i \leftarrow 0$  to  $m-1$  // preprocessing
05      $fp \leftarrow (10*fp + P[i]) \bmod q$ 
06      $ft \leftarrow (10*ft + T[i]) \bmod q$ 
07 for  $s \leftarrow 0$  to  $n - m$  // matching
08     if  $fp = ft$  then // run a loop to compare strings
09         if  $P[0..m-1] = T[s..s+m-1]$  return  $s$ 
10      $ft \leftarrow ((ft - T[s]*c)*10 + T[s+m]) \bmod q$ 
11 return -1
```

Analysis

- If q is a prime, the hash function distributes m -digit strings evenly among the q values
 - Thus, only every q^{th} value of shift s will result in matching fingerprints (which will require comparing strings with $O(m)$ comparisons)
- Expected running time (if $q > m$):
 - Preprocessing: $O(m)$
 - Outer loop: $O(n-m)$
 - All inner loops: $\frac{n-m}{q}m = O(n-m)$
 - Total time: $O(n-m)$
- Worst-case running time: $O(nm)$

Rabin-Karp in Practice

- If the alphabet has d characters, interpret characters as radix- d digits (replace 10 with d in the algorithm).
- Choosing prime $q > m$ can be done with randomized algorithms in $O(m)$, or q can be fixed to be the largest prime so that 10^*q fits in a computer word.

FINITE AUTOMATA

Searching in n comparisons

- The goal: each character of the text is compared only once!
- Problem with the naïve algorithm:
 - Forgets what was learned from a partial match!
 - Examples:
 - $T = \text{"Tweedledee and Tweedledum"}$ and $P = \text{"Tweedledum"}$
 - $T = \text{"pappappappar"}$ and $P = \text{"pappar"}$

Finite automaton search

input

state

	a	b	c	P
0	<u>1</u>	0	0	a
1	1	<u>2</u>	0	b
2	<u>3</u>	0	0	a
3	1	<u>4</u>	0	b
4	<u>5</u>	0	0	a
5	1	4	<u>6</u>	c
6	<u>7</u>	0	0	a
7	1	2	0	

i --	1	2	3	4	5	6	7	8	9	10	11	
T[i] --	a	b	a	b	a	b	a	c	a	b	a	
state $\phi(i)$	0	1	2	3	4	5	4	5	6	7	2	3

Processing time takes $\Theta(n)$.

But have to first construct FA.

Main Issue: How to construct FA?

Need some Notation ...

$\phi(w)$ = state FA ends up in after processing w .

Example: $\phi(abab) = 4$.

$\sigma(x) = \max\{k: P_k \text{ suf } x\}$. Called the **suffix function**.

Examples: Let $P = ab$.

$$\sigma(\epsilon) = 0$$

$$\sigma(ccaca) = 1$$

$$\sigma(ccab) = 2$$

Note: If $|P| = m$, then $\sigma(x) = m$ indicates a match.

T: a b a b b a b b a c ...

States: 0 1 **m** **m**

 ↑ ↑
 match **match**

FA Construction

Given: $P[1..m]$ Let $Q = \text{states} = \{0, 1, \dots, m\}$.

Define transition function δ as follows:

$\delta(q, a) = \sigma(P_q a)$ for each q and a .

Example: $\delta(5, b) = \sigma(P_5 b)$ ($P = \text{ababaca}$)
 $= \sigma(\text{ababab})$
 $= 4$

Intuition: Encountering a 'b' in state 5 means the current substring doesn't match. But, you know this substring ends with "abab" -- and this is the longest suffix that matches the beginning of P . Thus, we go to state 4 and continue processing "abab..." .

$P = ababaca$

$m=7; Q=\{0,1,2,3,4,5,6,7\}$

-

BITAP ALGORITHM: SHIFT/AND

The *Shift-And* Method

- Define M to be a binary n by m matrix such that:

$M(i,j) = 1$ iff the first i characters of P exactly match the i characters of T ending at character j .

$$M(i,j) = 1 \text{ iff } P[1 \dots i] \equiv T[j-i+1 \dots j]$$

The *Shift-And* Method

- Let **T** = **california**
- Let **P** = **for**

M =

	1	2	3	4	5	6	7	8	9	m = 10
1	0	0	0	0	1	0	0	0	0	0
2	0	0	0	0	0	1	0	0	0	0
3	0	0	0	0	0	0	1	0	0	0

- $M(i,j) = 1$ iff the first i characters of **P** exactly match the i characters of **T** ending at character j .

How to construct M

- We will construct M column by column.
- Two definitions:
- $\text{Bit-Shift}(j-1)$ is the vector derived by *shifting* the vector for column $j-1$ down by one and setting the first bit to 1.
- Example:

$$\text{BitShift}\left(\begin{pmatrix} 0 \\ 1 \\ 1 \\ 0 \\ 1 \end{pmatrix}\right) = \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix}$$

How to construct M

- We define the n -length binary vector $U(x)$ for each character x in the alphabet. $U(x)$ is set to 1 for the positions in P where character x appears.
- Example:

$$P = \text{abaac} \quad U(a) = \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix} \quad U(b) = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} \quad U(c) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

How to construct M

- Initialize column 0 of M to all zeros
- For $j > 1$ column j is obtained by

$$M(j) = \textit{BitShift}(j-1) \wedge U(T(j))$$

An example $j = 1$

1 2 3 4 5 6 7 8 9 10
T = x a b x a b a a c a
1 2 3 4 5
P = a b a a c

	init	1	2	3	4	5	6	7	8	9	10
1	0	0									
2	0	0									
3	0	0									
4	0	0									
5	0	0									

$$U(x) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

$$BitShift(0) \& U(T(1)) = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \& \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

An example $j = 2$

1 2 3 4 5 6 7 8 9 10

T = x a b x a b a a c a

1 2 3 4 5

P = a b a a c

		1	2	3	4	5	6	7	8	9	10
1	0	0	1								
2	0	0	0								
3	0	0	0								
4	0	0	0								
5	0	0	0								

$$U(a) = \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix}$$

$$BitShift(1) \& U(T(2)) = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \& \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

An example $j = 3$

1 2 3 4 5 6 7 8 9 10

T = x a b x a b a a c a

1 2 3 4 5

P = a b a a c

		1	2	3	4	5	6	7	8	9	10
1	0	0	1	0							
2	0	0	0	1							
3	0	0	0	0							
4	0	0	0	0							
5	0	0	0	0							

$$U(b) = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

$$BitShift(2) \& U(T(3)) = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} \& \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

An example $j = 8$

1 2 3 4 5 6 7 8 9 10

T = x a b x a b a a c a

1 2 3 4 5

P = a b a a c

		1	2	3	4	5	6	7	8	9	10
1	0	0	1	0	0	1	0	1	1		
2	0	0	0	1	0	0	1	0	0		
3	0	0	0	0	0	0	0	1	0		
4	0	0	0	0	0	0	0	0	1		
5	0	0	0	0	0	0	0	0	0		

$$U(a) = \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix}$$

$$BitShift(7) \& U(T(8)) = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 1 \\ 0 \end{pmatrix} \& \begin{pmatrix} 1 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}$$

Correctness

- For $i > 1$, Entry $M(i,j) = 1$ iff
 - 1) The first $i-1$ characters of P match the $i-1$ characters of T ending at character $j-1$.
 - 2) Character $P(i) \equiv T(j)$.
- 1) is true when $M(i-1,j-1) = 1$.
- 2) is true when the i^{th} bit of $U(T(j)) = 1$.
- The algorithm computes the ***and*** of these two bits.

Correctness

1 2 3 4 5 6 7 8 9 10

T = x a b x a b a a c a

a b a a c

		1	2	3	4	5	6	7	8	9	10
1	0	0	1	0	0	1	0	1	1	0	1
2	0	0	0	1	0	0	1	0	0	0	0
3	0	0	0	0	0	0	0	1	0	0	0
4	0	0	0	0	0	0	0	0	1	0	0
5	0	0	0	0	0	0	0	0	0	1	0

- $M(4,8) = 1$, this is because **a b a a** is a prefix of P of length 4 that ends at position 8 in T .
- Condition 1) – We had **a b a** as a prefix of length 3 that ended at position 7 in $T \leftrightarrow M(3,7) = 1$.
- Condition 2) – The fourth bit of P is the eighth bit of $T \leftrightarrow$ The fourth bit of $U(T(8)) = 1$.

How much did we pay?

- Formally the running time is $\Theta(mn)$.
 - However, the method is very efficient if m is the size of a single or a few computer words.
 - Furthermore only two columns of M are needed at any given time. Hence, the space used by the algorithm is $O(m)$ for $m=|P|$.
-
